Understanding APIs

Definition wikipedia

Application programming interface (API) is a way for two or more computer programs or components to communicate with each other. It is a type of software interface, offering a service to other pieces of software.

Definition ChatGPT

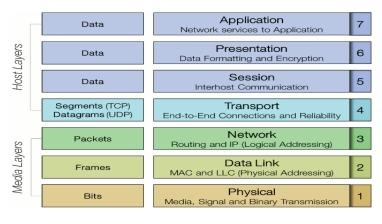

API (Application Programming Interface) is a set of rules, protocols, and tools for building software applications. It specifies how software components should interact and is used to enable the integration between different software systems.

History wikipedia

The term "application program interface" is first recorded in a paper called Data structures and techniques for remote computer graphics in 1968. The authors use the term to describe the interaction of an application "Graphics Program" with the rest of the computer system.

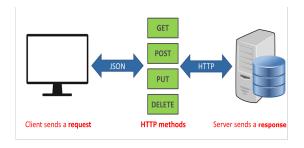

Understanding APIs OSI Model

The open systems interconnection (OSI) model is a conceptual model created for Standardization which enables diverse communication systems to communicate using standard protocols.

There are several types of API, each one serves specific use case.

 Public APIs (Open APIs)
 The APIs are publicly available and can be designed in various ways, taking security into account. However,
 the main priority is to ensure they are easily consumable by as many clients as possible.

- Partner APIs

Specialized interfaces that enable organizations to access data and service offerings across businesses (B2B) in order to create unique features within their own applications or services by utilizing a partner's resources.

Internal APIs

Intended for use internally by the organizations own developers. These APIs facilitate the transmission of data between different components of a system, enabling process automation.

The types can be designed and developed using two ways

- API Architectural Style,
- API Standard Protocol.

Understanding APIs (API Architecture vs API Protocols)

API Architecture Style

It refers to the high-level structural design of the API. It encompasses the standards, and best practices governing how the API is developed, how it interacts with other systems, and how it exposes its functionality and data.

Example: REST

No Restrictions

Architectural style is sensitive to change and enhancement; it relies more on human experience.

API Protocol

It refers to a set of rules and standards used for communication between various software components. The protocol dictates how requests and responses are formatted and transmitted, and what are the restrictions of the communication.

Example: SOAP

 SOAP (Simple Object Access Protocol) is a protocol used for exchanging structured information in web services in computer networks.

- SOAP (Simple Object Access Protocol) is a protocol used for exchanging structured information in web services in computer networks.
- It's a standards-based web services access protocol that has been around for a long time.

- It relies on XML as its message format and usually relies on other application layer protocols, most notably Hypertext Transfer Protocol (HTTP) and Simple Mail Transfer Protocol (SMTP), for message negotiation and transmission.

```
<?xml version="1.0"?>
       <soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">

No Push Capabilities	Server Push

Understanding APIs (gRPC Protocol)

- gRPC is a modern open source high performance Remote Procedure Call (RPC) framework that was developed in Google.
- gRPC can use protocol buffers as its underlying message interchange format.
- gRPC is based around the idea of defining a service, specifying the methods that can be called remotely with their parameters and return types.
- On the server side, the server implements this interface and runs a gRPC server to handle client calls.
- On the client side, the client has a stub (referred to as just a client in some languages) that provides the same methods
 as the server.

Understanding APIs (Protocol Buffers)

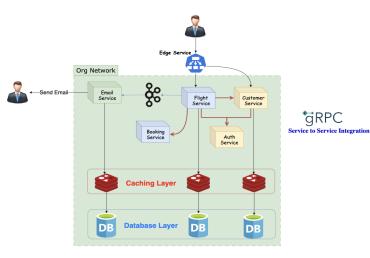

- Protocol Buffers are a language-neutral, platform-neutral extensible mechanism for serializing structured data.
- The file that includes the definition is .proto file

```
message Person {
string name = 1;
int32 id = 2;
bool has_kids = 3;
optional string email = 4;
}
```

Understanding APIs (RESTful API)

REST API

- In 2000, Roy Fielding proposed Representational State Transfer (REST) as an architectural approach to designing web services
- REST is independent of any underlying protocol and is not necessarily tied to HTTP
- REST is an architectural style for building distributed systems based on hypermedia

Primary Goal

REST API doesn't bind the implementation to any specific implementation, the API could be written in \mathbf{Go} , and the client can use any language or tools.

Example

To **GET** an order, API URI might look like https://adventure-works.com/orders/1 Client response {"orderId":1,"orderValue":99.90,"productId":1,"quantity":1}
